

DEVON RIVER AUTHORITYRIVER DART SCALE READING INVESTIGATION - 1971

The object of this investigation is to examine by means of scale reading the biology of age classes of the salmon population of the River Dart.

In 1967 the final report on a five-year scale reading programme was summarised. At that time it was considered that sufficient information had been gathered to help with restocking programmes and the management of salmon in the River Dart.

Since that time the advent of U.D.N. and the increase in high-seas netting for salmon caused the Authority to reconsider the scale reading programme.

In 1971 a further scale reading programme was started in an attempt to monitor changing patterns in salmon runs that may be caused by the new influences.

As the most important factor is the fish that are cropped, this investigation will be limited to scales collected in the open fishing season and also, for the time being, related to the net catches only as U.D.N. has reduced rod catches to a level where scales from that source would not be statistically viable.

For ease of reference the report is arranged in sections, as in previous years, and tables referred to in the report form an appendix, except for Table 1 which is included in the text on page 2.

- A - METHODS
- B - NET COLLECTION
- C - GENERAL
- D - DISCUSSION

A. METHODSCollection of Scales

Scales were collected from fish taken during the normal open season, which in 1971 was:

Nets 15th March - 16th August.

A weekly close time was in operation for the nets from 6 a.m. on Saturday to 6 a.m. on the following Monday, a period of 48 hours.

Eighteen licences were issued for draft or seine nets for the 1971 season.

Number of Scales Collected

517 (671) sets were collected from NET caught fish.

Totals for the 1967 season are shown in brackets.

Examination of Material

The techniques of mounting, projecting and reading were the same as those employed in previous years.

Inevitably some sets of scales were received which, for various reasons, could not be read or recorded and these were discounted from the final totals used for statistical analysis.

B. THE NET COLLECTION

An examination of Table 1 shows that scales were collected from over half (76.4%) of the total number of fish reported to have been taken by nets in 1971.

Reference to previous reports shows that in other seasons overall percentage samples were:

1962	57.6%	(scales collected/total declared catch)
1963	72.6%	" " " " "
1964	64.7%	" " " " "
1965	44.1%	" " " " "
1966	43.9%	" " " " "
1967	56.5%	" " " " "
1971	76.4%	" " " " "

The effectiveness of sampling effort was very high at the beginning of the season and continued to be very satisfactory for the remainder of the season. The lowest percentage sample was submitted for August but this is felt, in the opinion of the writer, to be a perfectly adequate and valid sample of the fish running in this month.

TABLE 1 - Comparison of Monthly Net Catches with Scale Sample Collected

Month	Number Caught	Scales Collected	% Total
March	7	6	85.7
April	45	37	82.2
May	127	111	87.4
June	190	131	68.9
July	230	180	78.3
August	78	52	66.7
Total	677	517	76.4

Composition of Catch

Tables 2, 3, 4 and 5 in the Appendix set out the statistics for the net collection and some of these results are illustrated in histogram form in Figures 1, 2, 3 and 4. It can be seen from these tabulated results that:

- (i) The majority of the scales in the collection were classified into the three groups of fish; grilse, small spring and small summer fish. Together these year classes make up 98.4% of the collection.
- (ii) The trend for grilse to be an increased part of the catch continues, now making up 24.2%. However, small spring fish, at 58% of the catch, are at the highest ever recorded group level. The small summer fish group is not well represented in the 1971 sample, making up only 16.5% of the catch, compared with between 30-50% in the early 1960's.
- (iii) The only other two groups in the 1971 collection are large spring fish and previous spawners, but both groups make only a very small part of the collection.
- (iv) The largest and smallest fish in the year classes can be scheduled as follows (date of capture in brackets):

Year Class	Smallest	Largest
1+ (Grilse)	3 lbs (6.7.71)	11 lbs (6.7.71)
2 (Small Spring Fish)	5 lbs (16.8.71)	17 lbs (4.7.71)
2+ (Small Summer Fish)	2 @ 6½ lbs (June)	15 lbs (16.8.71)
3 (Large Spring Fish)	12 lbs (14.5.71)	13½ lbs (19.4.71)
Sm (Previous Spawners)	8 lbs (10.8.71)	20 lbs (1.6.71)

The headings 'Smallest' and 'Largest' refer to weight only.

The average weights of the various year classes recorded are as follows (averages for 1962, 1963, 1964, 1965, 1966 and 1967 are included as a basis for comparison):

Year Class	1962	1963	1964	1965	1966	1967	1971
1+	6.15	5.95	5.72	5.61	6.1	6.26	5.6
2	9.31	10.01	8.73	9.19	9.7	9.78	9.5
2+	9.98	11.13	9.60	9.61	10.5	10.47	10.4
3	15.3	15.4	15.1	13.8	16.4	15.42	12.8 (3)
3+	20.0 (1)	19.3 (3)	17.2 (2)	-	16.0 (2)	-	-
Sm	16.6	16.4	13.8 (9)	15.8	13.7 (6)	15.56 (9)	13.3 (5)

Where the number of fish used for calculating the average weight is below 10, it is shown in brackets.

Time of Run

Table 5 and Figure 4 in the Appendix show the distribution of sea-age class captures throughout the season and from these it can be seen that:

- (i) Scales from fish caught in March were from large spring fish - 16%, and small spring fish - 66%.
- (ii) Of the year classes sampled in April 94% were small spring fish, 2.7% large spring fish and 2.7% previously spawned fish.
- (iii) 94% of the fish sampled in May were small spring fish and 3% were small summer fish which began to appear at the beginning of the month.
- (iv) Grilse began to appear in June, making up 9% of the sample. Small spring fish were still running; they were represented as 77% of the sample.
- (v) Grilse became the most sampled year class in July and 44% were of this year class. 28% of the July sample were small spring fish and 28% small summer fish.
- (vi) 59% of the fish sampled in August were grilse and 23% small summer fish.

C. GENERAL

Table 4 shows the age of smolts at the time of migration to sea. It can be seen that the vast majority of parr become smolts at two years old. A very few fish migrated after spending three years in the river and still fewer after only one year of river life.

D. DISCUSSION

The results of the 1971 season's investigation show a pattern of basic information which is comparable to investigations of previous years. The results can be summarised as follows:

- (a) Grilse make up one quarter of the collection.
- (b) The dominant group in 1971 was the small spring fish.
- (c) Small summer fish make up a much smaller proportion of the net catches.

No attempt has been made in the season's investigation to cover any fish running into the river outside the normal open seasons for nets and rod and line.

ACKNOWLEDGEMENTS

The Authority would like to thank all persons assisting in this scale reading investigation, particularly the netsmen for their efforts in taking scale samples; scales were taken from over three-quarters of the season's catch.

TABLE 2 Sea-Age Classes and Weights

Class	Scale Sample	% of Total	Total Weight of Class(lbs)	% of Total
1+	122	23.6	688	15.1
